

ABSTRACT OF THE DISCLOSURE

DIRECT SYNTHESIS OF OXIDE NANOSTRUCTURES OF LOW-MELTING METALS

5 The bulk synthesis of highly crystalline noncatalytic low
melting metals such as β -gallium oxide tubes, nanowires, and
nanopaintbrushes is accomplished using molten gallium and microwave
plasma containing a mixture of monoatomic oxygen and hydrogen.
Gallium oxide nanowires were 20-100 nm thick and tens to hundreds
10 of microns long. Transmission electron microscopy (TEM) revealed
the nanowires to be highly crystalline and devoid of any structural
defects. Results showed that multiple nucleation and growth of
gallium oxide nanostructures can occur directly out of molten
gallium exposed to appropriate composition of hydrogen and oxygen
15 in the gas phase. These gallium oxide nanostructures are of
particular interest for opto-electronic devices and catalytic
applications.
